11.3 The Law of Cosines

In Section 11.2, we developed the Law of Sines (Theorem 11.2) to enable us to solve triangles in the ‘Angle-Angle-Side’ (AAS), the ‘Angle-Side-Angle’ (ASA) and the ambiguous ‘Angle-Side-Side’ (ASS) cases. In this section, we develop the Law of Cosines which handles solving triangles in the ‘Side-Angle-Side’ (SAS) and ‘Side-Side-Side’ (SSS) cases.\(^1\) We state and prove the theorem below.

**Theorem 11.5. Law of Cosines:** Given a triangle with angle-side opposite pairs \((\alpha, a), (\beta, b)\) and \((\gamma, c)\), the following equations hold

\[
\begin{align*}
    a^2 &= b^2 + c^2 - 2bc \cos(\alpha) \\
    b^2 &= a^2 + c^2 - 2ac \cos(\beta) \\
    c^2 &= a^2 + b^2 - 2ab \cos(\gamma)
\end{align*}
\]

or, solving for the cosine in each equation, we have

\[
\begin{align*}
    \cos(\alpha) &= \frac{b^2 + c^2 - a^2}{2bc} \\
    \cos(\beta) &= \frac{a^2 + c^2 - b^2}{2ac} \\
    \cos(\gamma) &= \frac{a^2 + b^2 - c^2}{2ab}
\end{align*}
\]

To prove the theorem, we consider a generic triangle with the vertex of angle \(\alpha\) at the origin with side \(b\) positioned along the positive \(x\)-axis.

From this set-up, we immediately find that the coordinates of \(A\) and \(C\) are \(A(0,0)\) and \(C(b,0)\). From Theorem 10.3, we know that since the point \(B(x, y)\) lies on a circle of radius \(c\), the coordinates

\(^1\)Here, ‘Side-Angle-Side’ means that we are given two sides and the ‘included’ angle - that is, the given angle is adjacent to both of the given sides.
of B are \(B(x, y) = B(c \cos(\alpha), c \sin(\alpha))\). (This would be true even if \(\alpha\) were an obtuse or right angle so although we have drawn the case when \(\alpha\) is acute, the following computations hold for any angle \(\alpha\) drawn in standard position where \(0 < \alpha < 180^\circ\).) We note that the distance between the points \(B\) and \(C\) is none other than the length of side \(a\). Using the distance formula, Equation 1.1, we get

\[
a = \sqrt{(c \cos(\alpha) - b)^2 + (c \sin(\alpha) - 0)^2}
\]

\[
a^2 = (\sqrt{(c \cos(\alpha) - b)^2 + c^2 \sin^2(\alpha)})^2
\]

\[
a^2 = (c \cos(\alpha) - b)^2 + c^2 \sin^2(\alpha)
\]

\[
a^2 = c^2 \cos^2(\alpha) - 2bc \cos(\alpha) + b^2 + c^2 \sin^2(\alpha)
\]

\[
a^2 = c^2 (1) + b^2 - 2bc \cos(\alpha)
\]

\[
a^2 = c^2 + b^2 - 2bc \cos(\alpha)
\]

The remaining formulas given in Theorem 11.5 can be shown by simply reorienting the triangle to place a different vertex at the origin. We leave these details to the reader. What’s important about \(a\) and \(\alpha\) in the above proof is that \((\alpha, a)\) is an angle-side opposite pair and \(b\) and \(c\) are the sides adjacent to \(\alpha\) – the same can be said of any other angle-side opposite pair in the triangle. Notice that the proof of the Law of Cosines relies on the distance formula which has its roots in the Pythagorean Theorem. That being said, the Law of Cosines can be thought of as a generalization of the Pythagorean Theorem. If we have a triangle in which \(\gamma = 90^\circ\), then \(\cos(\gamma) = \cos (90^\circ) = 0\) so we get the familiar relationship \(c^2 = a^2 + b^2\). What this means is that in the larger mathematical sense, the Law of Cosines and the Pythagorean Theorem amount to pretty much the same thing.\(^2\)

**Example 11.3.1.** Solve the following triangles. Give exact answers and decimal approximations (rounded to hundredths) and sketch the triangle.

1. \(\beta = 50^\circ, a = 7\) units, \(c = 2\) units
2. \(a = 4\) units, \(b = 7\) units, \(c = 5\) units

**Solution.**

1. We are given the lengths of two sides, \(a = 7\) and \(c = 2\), and the measure of the included angle, \(\beta = 50^\circ\). With no angle-side opposite pair to use, we apply the Law of Cosines. We get \(b^2 = 7^2 + 2^2 - 2(7)(2) \cos (50^\circ)\) which yields \(b = \sqrt{53 - 28 \cos (50^\circ)} \approx 5.92\) units. In order to determine the measures of the remaining angles \(\alpha\) and \(\gamma\), we are forced to used the derived value for \(b\). There are two ways to proceed at this point. We could use the Law of Cosines again, or, since we have the angle-side opposite pair \((\beta, b)\) we could use the Law of Sines. The advantage to using the Law of Cosines over the Law of Sines in cases like this is that unlike the sine function, the cosine function distinguishes between acute and obtuse angles. The cosine of an acute is positive, whereas the cosine of an obtuse angle is negative. Since the sine of both acute and obtuse angles are positive, the sine of an angle alone is not

\(^2\)This shouldn’t come as too much of a shock. All of the theorems in Trigonometry can ultimately be traced back to the definition of the circular functions along with the distance formula and hence, the Pythagorean Theorem.
Applications of Trigonometry

enough to determine if the angle in question is acute or obtuse. Since both authors of the textbook prefer the Law of Cosines, we proceed with this method first. When using the Law of Cosines, it’s always best to find the measure of the largest unknown angle first, since this will give us the obtuse angle of the triangle if there is one. Since the largest angle is opposite the longest side, we choose to find $\alpha$ first. To that end, we use the formula $\cos(\alpha) = \frac{b^2 + c^2 - a^2}{2bc}$ and substitute $a = 7$, $b = \sqrt{53 - 28 \cos(50^\circ)}$ and $c = 2$. We get

$$\cos(\alpha) = \frac{2 - 7 \cos(50^\circ)}{\sqrt{53 - 28 \cos(50^\circ)}}$$

Since $\alpha$ is an angle in a triangle, we know the radian measure of $\alpha$ must lie between 0 and $\pi$ radians. This matches the range of the arccosine function, so we have

$$\alpha = \arccos\left(\frac{2 - 7 \cos(50^\circ)}{\sqrt{53 - 28 \cos(50^\circ)}}\right) \text{ radians} \approx 114.99^\circ$$

At this point, we could find $\gamma$ using $\gamma = 180^\circ - \alpha - \beta \approx 180^\circ - 114.99^\circ - 50^\circ = 15.01^\circ$, that is if we trust our approximation for $\alpha$. To minimize propagation of error, however, we could use the Law of Cosines again, in this case using $\cos(\gamma) = \frac{a^2 + c^2 - b^2}{2ac}$. Plugging in $a = 7$, $b = \sqrt{53 - 28 \cos(50^\circ)}$ and $c = 2$, we get $\gamma = \arccos\left(\frac{7 - 2 \cos(50^\circ)}{\sqrt{53 - 28 \cos(50^\circ)}}\right)$ radians $\approx 15.01^\circ$. We sketch the triangle below.

As we mentioned earlier, once we’ve determined $b$ it is possible to use the Law of Sines to find the remaining angles. Here, however, we must proceed with caution as we are in the ambiguous (ASS) case. It is advisable to first find the smallest of the unknown angles, since we are guaranteed it will be acute. In this case, we would find $\gamma$ since the side opposite $\gamma$ is smaller than the side opposite the other unknown angle, $\alpha$. Using the angle-side opposite pair $(\beta, b)$, we get $\frac{\sin(\gamma)}{2} = \frac{\sin(50^\circ)}{\sqrt{53 - 28 \cos(50^\circ)}}$. The usual calculations produces $\gamma \approx 15.01^\circ$ and $\alpha = 180^\circ - \beta - \gamma \approx 180^\circ - 50^\circ - 15.01^\circ = 114.99^\circ$.

2. Since all three sides and no angles are given, we are forced to use the Law of Cosines. Following our discussion in the previous problem, we find $\beta$ first, since it is opposite the longest side, $b$. We get $\cos(\beta) = \frac{a^2 + c^2 - b^2}{2ac} = -\frac{1}{5}$, so we get $\beta = \arccos\left(-\frac{1}{5}\right)$ radians $\approx 101.54^\circ$. As in

---

3 after simplifying .

4 Your instructor will let you know which procedure to use. It all boils down to how much you trust your calculator.

5 There can only be one obtuse angle in the triangle, and if there is one, it must be the largest.
the previous problem, now that we have obtained an angle-side opposite pair \((\beta, b)\), we could proceed using the Law of Sines. The Law of Cosines, however, offers us a rare opportunity to find the remaining angles using only the data given to us in the statement of the problem. Using this, we get \(\gamma = \arccos \left(\frac{5}{7}\right)\) radians \(\approx 44.42^\circ\) and \(\alpha = \arccos \left(\frac{29}{35}\right)\) radians \(\approx 34.05^\circ\).

We note that, depending on how many decimal places are carried through successive calculations, and depending on which approach is used to solve the problem, the approximate answers you obtain may differ slightly from those the authors obtain in the Examples and the Exercises. A great example of this is number 2 in Example 11.3.1, where the approximate values we record for the measures of the angles sum to 180.01°, which is geometrically impossible. Next, we have an application of the Law of Cosines.

**Example 11.3.2.** A researcher wishes to determine the width of a vernal pond as drawn below. From a point \(P\), he finds the distance to the eastern-most point of the pond to be 950 feet, while the distance to the western-most point of the pond from \(P\) is 1000 feet. If the angle between the two lines of sight is 60°, find the width of the pond.

**Solution.** We are given the lengths of two sides and the measure of an included angle, so we may apply the Law of Cosines to find the length of the missing side opposite the given angle. Calling this length \(w\) (for width), we get \(w^2 = 950^2 + 1000^2 - 2(950)(1000)\cos(60^\circ) = 952500\) from which we get \(w = \sqrt{952500} \approx 976\) feet.
In Section 11.2, we used the proof of the Law of Sines to develop Theorem 11.4 as an alternate formula for the area enclosed by a triangle. In this section, we use the Law of Cosines to derive another such formula - Heron’s Formula.

**Theorem 11.6. Heron’s Formula:** Suppose \( a, b \) and \( c \) denote the lengths of the three sides of a triangle. Let \( s \) be the semiperimeter of the triangle, that is, let \( s = \frac{1}{2}(a + b + c) \). Then the area \( A \) enclosed by the triangle is given by

\[
A = \sqrt{s(s - a)(s - b)(s - c)}
\]

We prove Theorem 11.6 using Theorem 11.4. Using the convention that the angle \( \gamma \) is opposite the side \( c \), we have \( A = \frac{1}{2}ab\sin(\gamma) \) from Theorem 11.4. In order to simplify computations, we start by manipulating the expression for \( A^2 \).

\[
A^2 = \left(\frac{1}{2}ab\sin(\gamma)\right)^2 = \frac{1}{4}a^2b^2\sin^2(\gamma) = \frac{a^2b^2}{4} (1 - \cos^2(\gamma)) \text{ since } \sin^2(\gamma) = 1 - \cos^2(\gamma).
\]

The Law of Cosines tells us \( \cos(\gamma) = \frac{a^2+b^2-c^2}{2ab} \), so substituting this into our equation for \( A^2 \) gives

\[
A^2 = \frac{a^2b^2}{4} (1 - \cos^2(\gamma)) = \frac{a^2b^2}{4} \left[1 - \left(\frac{a^2+b^2-c^2}{2ab}\right)^2\right] = \frac{a^2b^2}{4} \left[1 - \left(\frac{a^2+b^2-c^2}{4a^2b^2}\right)^2\right] = \frac{a^2b^2}{4} \left[\frac{4a^2b^2 - (a^2+b^2-c^2)^2}{4a^2b^2}\right] = \frac{4a^2b^2 - (a^2+b^2-c^2)^2}{16} = \frac{(2ab)^2 - (a^2+b^2-c^2)^2}{16} = \frac{(2ab - [a^2+b^2-c^2]) (2ab + [a^2+b^2-c^2])}{16} \text{ difference of squares.}
\]

\[
= \frac{(c^2 - a^2 - 2ab - b^2) (a^2 + 2ab + b^2 - c^2)}{16}
\]
\[
A^2 = \frac{(c^2 - [a^2 - 2ab + b^2]) ([a^2 + 2ab + b^2] - c^2)}{16}
\]

\[
= \frac{(c^2 - (a - b)^2) ((a + b)^2 - c^2)}{16}
\]

perfect square trinomials.

\[
= \frac{(c - (a - b))(c + (a - b))((a + b) - c)((a + b) + c)}{16}
\]

difference of squares.

\[
= \frac{(b + c - a)(a + c - b)(a + b - c)(a + b + c)}{16}
\]

\[
= \frac{(b + c - a)}{2} \cdot \frac{(a + c - b)}{2} \cdot \frac{(a + b - c)}{2} \cdot \frac{(a + b + c)}{2}
\]

At this stage, we recognize the last factor as the semiperimeter, \( s = \frac{1}{2}(a + b + c) = \frac{a+b+c}{2} \). To complete the proof, we note that

\[
(s - a) = \frac{a + b + c}{2} - a = \frac{a + b + c - 2a}{2} = \frac{b + c - a}{2}
\]

Similarly, we find \((s - b) = \frac{a+c-b}{2}\) and \((s - c) = \frac{a+b-c}{2}\). Hence, we get

\[
A^2 = \frac{(b + c - a)}{2} \cdot \frac{(a + c - b)}{2} \cdot \frac{(a + b - c)}{2} \cdot \frac{(a + b + c)}{2}
\]

\[
= (s - a)(s - b)(s - c)s
\]

so that \( A = \sqrt{s(s - a)(s - b)(s - c)} \) as required.

We close with an example of Heron’s Formula.

**Example 11.3.3.** Find the area enclosed of the triangle in Example 11.3.1 number 2.

**Solution.** We are given \( a = 4 \), \( b = 7 \) and \( c = 5 \). Using these values, we find \( s = \frac{1}{2}(4 + 7 + 5) = 8 \), \((s - a) = 8 - 4 = 4 \), \((s - b) = 8 - 7 = 1\) and \((s - c) = 8 - 5 = 3\). Using Heron’s Formula, we get

\[
A = \sqrt{s(s - a)(s - b)(s - c)} = \sqrt{(8)(4)(1)(3)} = \sqrt{96} = 4\sqrt{6} \approx 9.80 \text{ square units}.
\]

\( \Box \)
